

Where anatomical laterality enters skeleton JEPA training

Completed experiments and the explicit-reflection extension have different evidence status.

Preparation occurs before fold assignment in the saved workflow; it fits no cross-clip statistics. Source separation precedes training sampling and augmentation.

Shape contract: transformations preserve the model tensor axes and carry validity alongside coordinates. Interpolation and resizing change the raw trajectory.
Initial control = untrained S-JEPA weights, with the same learned pose extractor and anatomical schema. Source folds do not establish participant separation.
